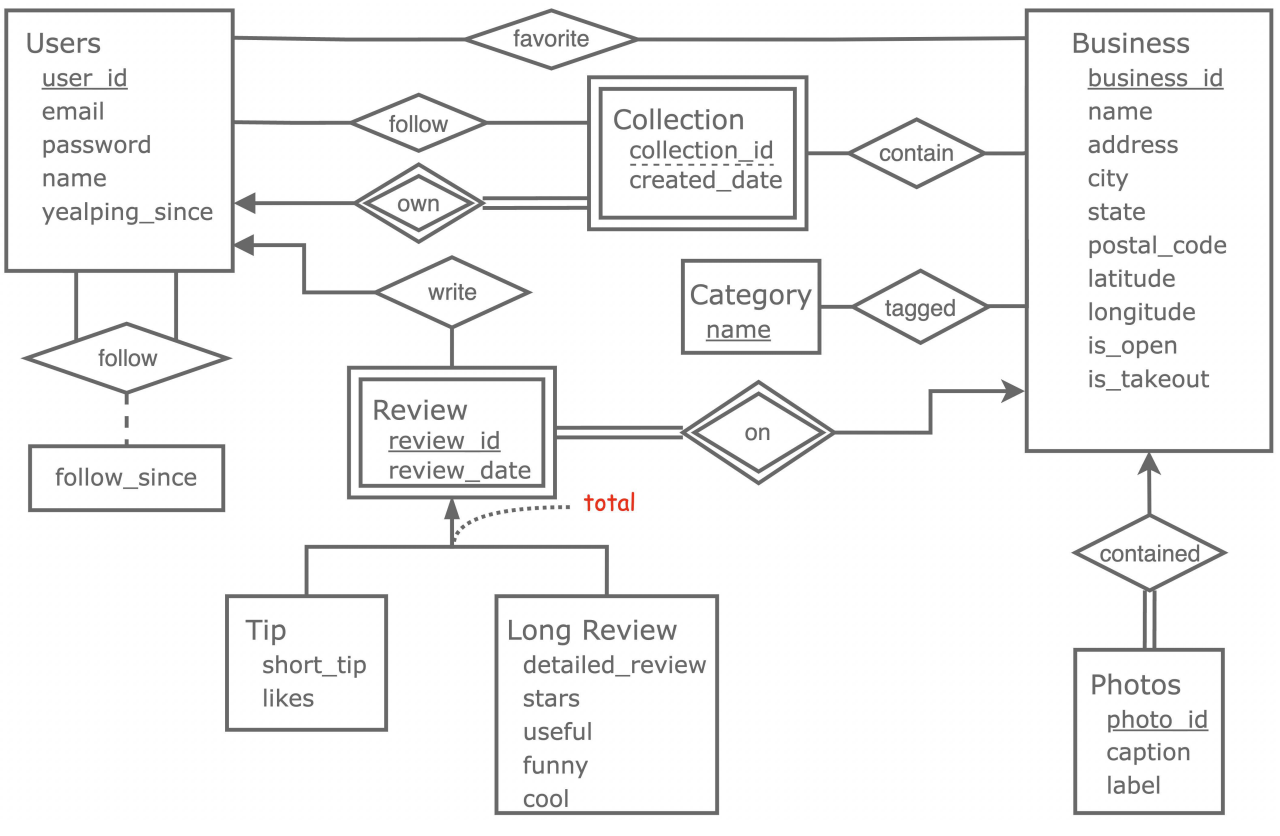
1 SQL schema

1.1 Latest ER diagram



All the changes we made from Part 1:

1. Delete attrbute `hour` in `Business` that requires json-type data importing with additional package like `pgspecial` (not allowed according to Ed #431 (https://edstem.org/us/courses/17037/discussion/1311446))
2. Change several `int` type id column into `text` to be consistent to the original dataset
3. Add `email` attribute of `Users` table in order to allow costumer to log in. The user_id will be a long text that only used in back-end.
4. Constrain the `password` attribute of `Users` to be in length [8, 16] in order to be more robust

1.2 CREATE commands

2 Data Preparation

In this part, we clean the Yelp dataset which contains mostly real-word data. That being said, we still need to generate some of the features, like `password` of User but all with reasonable assumptions described.

To re-run the code, download the Yelp Dataset (https://www.yelp.com/dataset/documentation/main) into a folder named "data" in the parent level of this file.

To access the cleaned data output from this part, we upload the dataframes in pickle format into a Google Drive (https://drive.google.com/drive/folders/1RvL6q7U1eeMvFVpNyH-dJ1AdkIf_E7l0?usp=sharing).

In [1]:
```
import pickle
pickle.HIGHEST_PROTOCOL = 4
import pandas as pd
import numpy as np
import random, string
from tqdm import tqdm
from datetime import datetime
```

2.1 Entity

users_follow.to_pickle("data/Users_follow_Users.pickle")
```

3 Data Population

To avoid directly populating sql table by pandas dataframe, we first generate this code automatically for all tables:

```
for each table:
    for each row in table:
        for each column in the table:
            extract the value
        %sql insert the row
```

and then run it!

3.1 Generate data population SQLs automatically

To avoid using additional package to achieve data importing from dataframe/csv, we automatic the method suggested in [ED #450 (https://edstem.org/us/courses/17037/discussion/1317472)](https://edstem.org/us/courses/17037/discussion/1317472) that INSERT tuples table-by-table and line-by-line.

In [4]:
```
import pandas as pd
import os
from google.colab import drive
drive.mount('/content/drive')
table_names = ['Users',
               'Collection_of_User',
               'Business',
               'Review_of_Business',
               'Category',
               'Photo_contained_Business',
               'Users_favorite_Business',
               'Users_follow_Collection',
               'Users_write_Review',
               'Collection_contain_Business',
               'Business_tagged_Category',
               'Users_follow_Users']

folder_path = "/content/drive/MyDrive/COMS 4111/Project 1/data"
file_names = [table_name + '.pickle' for table_name in table_names]
file_paths = [folder_path + '/' + file_name for file_name in file_names]
```

```
Drive already mounted at /content/drive; to attempt to forcibly remount, cal
l drive.mount("/content/drive", force_remount=True).
```

In [5]:
```
def get_code(table_name):
    df = pd.read_pickle(folder_path + '/' + table_name + '.pickle')
    data_import_code = f'{table_name} = pd.read_pickle(folder_path + "/{table_
name}.pickle")'

```

```
# Initial SQL INSERT code generating method we try without using the "for looop %s
ql"
table_nam = "Users"
for index, row in Users[:5].iterrows():
    INSERT_str = f"INSERT INTO {table_name} VALUES ("
    for column, column_type in zip(Users.columns, Users.dtypes):
        if column_type != 'object':
            INSERT_str += str(row[column]) + ", "
        else:
            INSERT_str += "'" + str(row[column]) + "', "
    INSERT_str = INSERT_str[:-2] + ");"
    print(INSERT_str)
```

4 Interesting SELECT queries.

4.1 Find the top 5 rated open resturant in average that has at least 5 review!

In [7]:
```
%%sql
SELECT name, address, city, round(AVG(stars), 2) AS average_stars
FROM Review_of_Business JOIN Business USING(business_id)
WHERE detailed_review IS NOT NULL AND is_open = True
GROUP BY business_id, name, address, city
HAVING count(*) >= 5
ORDER BY average_stars DESC LIMIT 5
```

```
 * postgresql://by2325:***@w4111.cisxo09blonu.us-east-1.rds.amazonaws.com/pr
oj1part2
5 rows affected.
```

Out[7]:

name	address	city	average_stars
BRŪ Florida Growler Bar	8729 Gunn Hwy	Odessa	5.00
Il Brother's Pizza & Restaurant	485 Baltimore Pike	Glen Mills	4.60
Tandoori Of India	1100 Jackson St	Philadelphia	4.00
Flying Cupcake Bakery	4026 E 82nd St	Indianapolis	3.20
Port of Subs	720 S Meadows Pkwy, Ste 4	Reno	3.00

4.2 Find the TOP 5 users with most fans

In [8]:
```
%%sql
WITH user_fans_cnt AS(
    SELECT follwee_user_id as user_id, COUNT(fan_user_id) as fans_cnt
    FROM Users_follow_Users
    GROUP BY follwee_user_id)
SELECT user_id, name, email, yealping_since, fans_cnt
FROM user_fans_cnt JOIN Users USING(user_id)
ORDER BY fans_cnt DESC, yealping_since ASC
LIMIT 5
```

```
 * postgresql://by2325:***@w4111.cisxo09blonu.us-east-1.rds.amazonaws.com/pr
oj1part2
5 rows affected.
```

Out[8]:

4.3 For all the categories, calculate the number of followers users through `Collection` that contain the restaurant

In [9]:
```
%%sql
WITH collection_cnt AS(
    SELECT followee_user_id AS collection_owner_id, collection_id, COUNT(fan_u
ser_id) AS fans_cnt
    FROM Users_follow_Collection
    GROUP BY followee_user_id, collection_id)

SELECT cate.name,
       COUNT(CONCAT(collection_owner_id, collection_id)) AS n_collections,
       SUM(fans_cnt) as total_fans_among_all_collections
FROM collection_cnt
    JOIN Collection_contain_Business USING(collection_owner_id, collection_id)
    JOIN Business USING(business_id)
    JOIN Business_tagged_Category cate USING(business_id)
WHERE is_open = True
GROUP BY cate.name
ORDER BY total_fans_among_all_collections DESC
```

```
 * postgresql://by2325:***@w4111.cisxo09blonu.us-east-1.rds.amazonaws.com/pr
oj1part2
16 rows affected.
```
